

Data Visualization

(A) Viewing Data from Static Google Charts (external html files)

You may see a gallery of charts in the following website

<https://developers.google.com/chart/interactive/docs/gallery>

Click on the chart type you want. There is 3 pieces of information you need to provide for a chart to be rendered. The below example will create a “ComboChart”

(i) In the <head > region of your page (or a link to an external .js file) place the following:

```
<script type="text/javascript" src="https://www.gstatic.com/charts/loader.js"> </script>
```

```
<script type="text/javascript">
```

```
    google.charts.load('current', {'packages':['corechart']});
```

```
    google.charts.setOnLoadCallback(drawVisualization);
```

```
// From this point embed the function (drawVisualization) that will render this chart of your choice
```

```
function drawVisualization() {
```

```
    // Some raw data (not necessarily accurate)
```

```
//1. Define your data ...stored in the variable array “data”. The first column holds the categories on which the numerical data series is based. The first row holds the names of each data column
```

```
    var data = google.visualization.arrayToDataTable([  
        ['Month', 'Bolivia', 'Ecuador', 'Madagascar', 'Papua New Guinea', 'Rwanda', 'Average'],  
        ['2004/05', 165, 938, 522, 998, 450, 614.6],  
        ['2005/06', 135, 1120, 599, 1268, 288, 682],  
        ['2006/07', 157, 1167, 587, 807, 397, 623],  
        ['2007/08', 139, 1110, 615, 968, 215, 609.4],  
        ['2008/09', 136, 691, 629, 1026, 366, 569.6]  
    ]);
```

```
// 2. define the options for this particular chart
```

```
    var options = {  
        title : 'Monthly Coffee Production by Country',  
        vAxis: {title: 'Cups'},  
        hAxis: {title: 'Month'},  
        seriesType: 'bars',  
        series: {5: {type: 'line'}}  
    };
```

```
};
```

// 3. Invoke the code to draw the chart. Be sure to supply the name of the <div> element where the chart is to be rendered.

```
var chart = new google.visualization.ComboChart(document.getElementById('chart_div')); ←
```

```
chart.draw(data, options);
```

```
}
```

```
</script> ←
```

//4. Don't forget to terminate the script with </script>

//5. In the body of the page be sure to create a <div> pair with the name you mentioned in #3 (e.g. chart_div)

e.g. <div id="chart_div" style="width: 900px; height: 500px;"></div> ←

The above example will create a chart that looks like

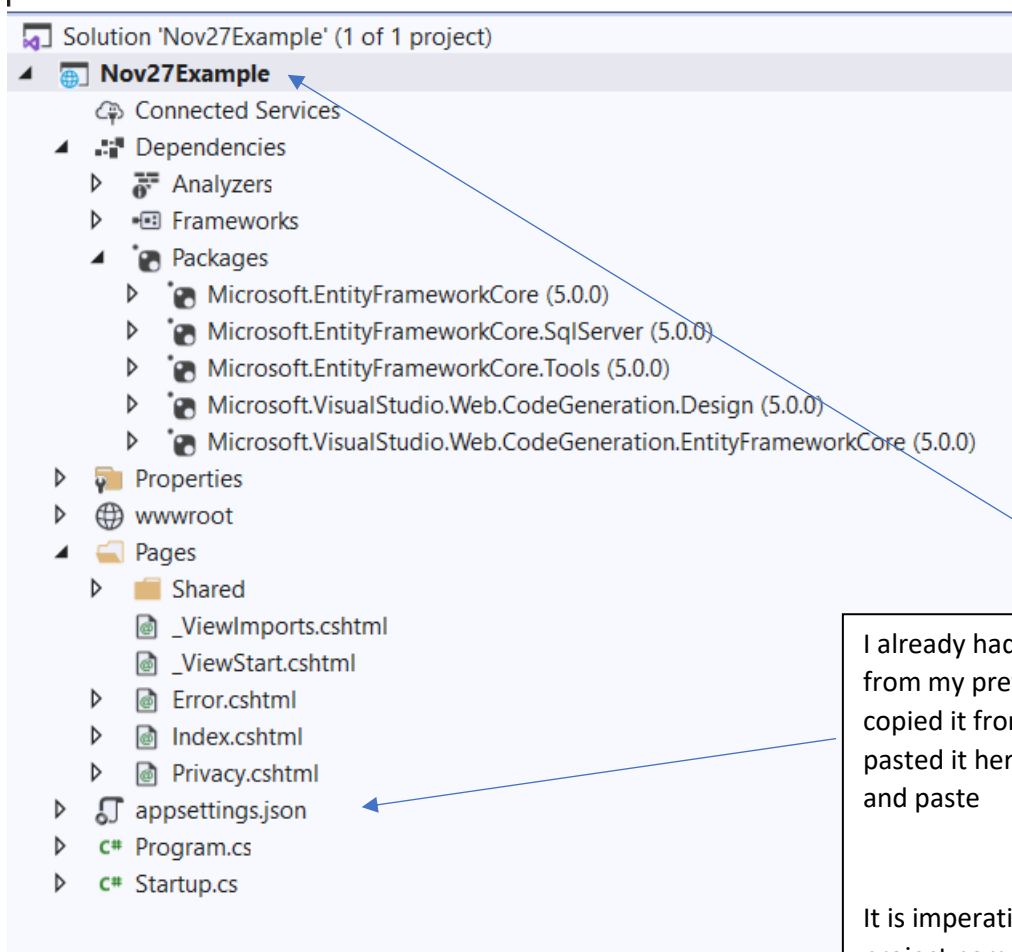

Practice doing this outside of your project on a simple html file, when you find the chart you like and data then incorporate examples of these in html documents within your project that could be reached from your layout page navigation links

For the rest of the visualization elements discussed in this document, be sure to create all your views, stored procedures (without parameters), stored procedures (with parameters).

Have all this ready along with your tables **before you scaffold your database** and create your context.cs file.

(B) GET YOUR DATA READY

I already had a functional appsettings.json from my previous project, so I selected it, copied it from the previous project and pasted it here by selecting the project name, and paste

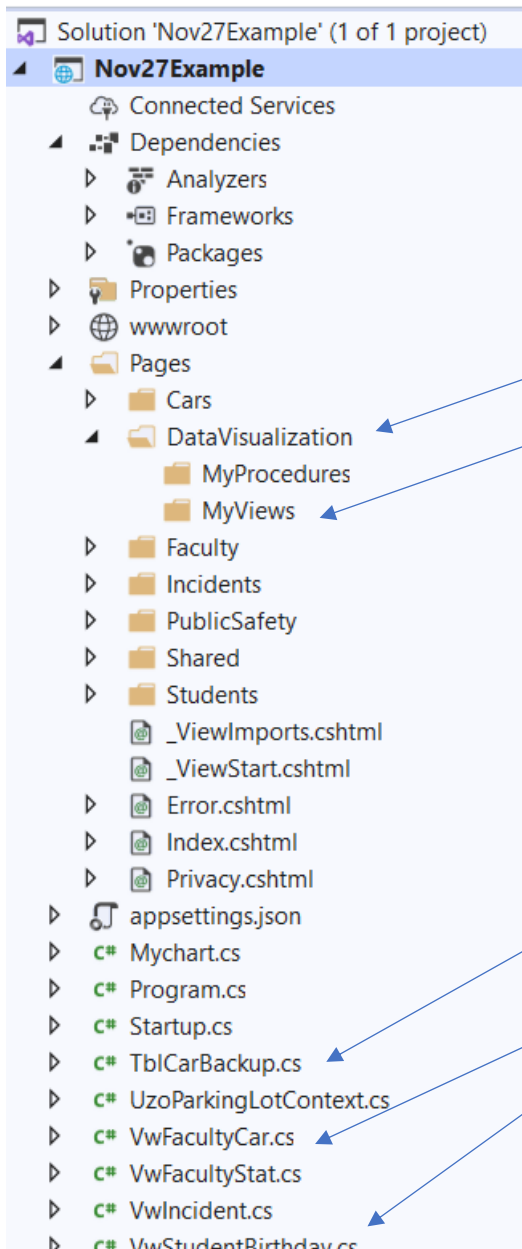

It is imperative to paste AFTER clicking on the project name to ensure that the apsetting files paste at the right level (directly in the main project folder)

After pasting your appsettings.json files, ensure you have the correct NuGet packages installed. See image above. Adjust your DbContext.cs and Startup.cs file as your other projects. Th startup.cs may be identical from your previous projects BUT the databaseContext.cs file may have changed due to new objects such as views, stored procedures in your database. So make the manual changes in these as you did in prior projects.

Then connect to SQL SERVER, make your connections trusted, as before,

Then run your Scaffold command from the NuGet PM console window,

All your tables, and views will be scaffolded. You will have o create model.cs files for each stored procedure, and amend your databaseContext.cs file to accommodate these stored procedure model files.

Create new folders, one for your views and another for your stored procedures, or however you choose to navigate. Create your CRUD pages as before in the appropriate folders.
Move your view.cs files into the folder you made for your views.
I made a DataVisualization folder in which I placed a folder for views and another for procedures. This is how I choose to navigate from my main page

Remove any scaffolded file you have no use for. Which were made from tables in your database irrelevant to this project

These view vw.cs files will be moved into my MyViews folder

Your typical view.cs file looks like this

```
using System;
using System.Collections.Generic;

#nullable disable

namespace Nov27Example
{
    2 references
    public partial class VwStudentMercede
    {
        1 reference
        public string FName { get; set; }
        1 reference
        public string Lname { get; set; }
        1 reference
        public string Make { get; set; }
    }
}
```

If you choose to rename your column names as opposed to using the table column names, this is where you specify it. You can also specify the way you want the data displayed if you have a numeric value you want to display with so many decimal places.

To do this you need to add

using System.ComponentModel.DataAnnotations;

```

VwStudentMercede.cs
Nov27Example
1  using System;
2  using System.Collections.Generic;
3  using System.ComponentModel.DataAnnotations;
4  #nullable disable
5
6  namespace Nov27Example
7  {
8      2 references
9      public partial class VwStudentMercede
10     {
11         [Display(Name = "First Name")]
12         1 reference
13         public string Fname { get; set; }
14         [Display(Name = "Last Name")]
15         1 reference
16         public string Lname { get; set; }
17         [Display(Name = "Car Brand")]
18         1 reference
19         public string Make { get; set; }
20     }
21 }

```

add
using System.ComponentModel.DataAnnotations;
put [Display(Name = " your preferred column name")]
immediately above specified field

Do this for each view display view.cs file for each view you want modified.

```

1  using System;
2  using System.Collections.Generic;
3  using System.ComponentModel.DataAnnotations;
4  #nullable disable
5
6  namespace Nov13PartB
7  {
8      4 references
9      public partial class VwStudentBirthday
10     {
11         [Display(Name = "First Name")]
12         3 references
13         public string FirstName { get; set; }
14         [Display(Name = "Last Name")]
15         3 references
16         public string LastName { get; set; }
17
18         [DisplayFormat(DataFormatString = "{0:dd MMM yyyy}")]
19         3 references
20         public DateTime? Birthday { get; set; }
21
22         public static implicit operator VwStudentBirthday(TblCar v)
23         {
24             throw new NotImplementedException();
25         }
26     }
27 }

```

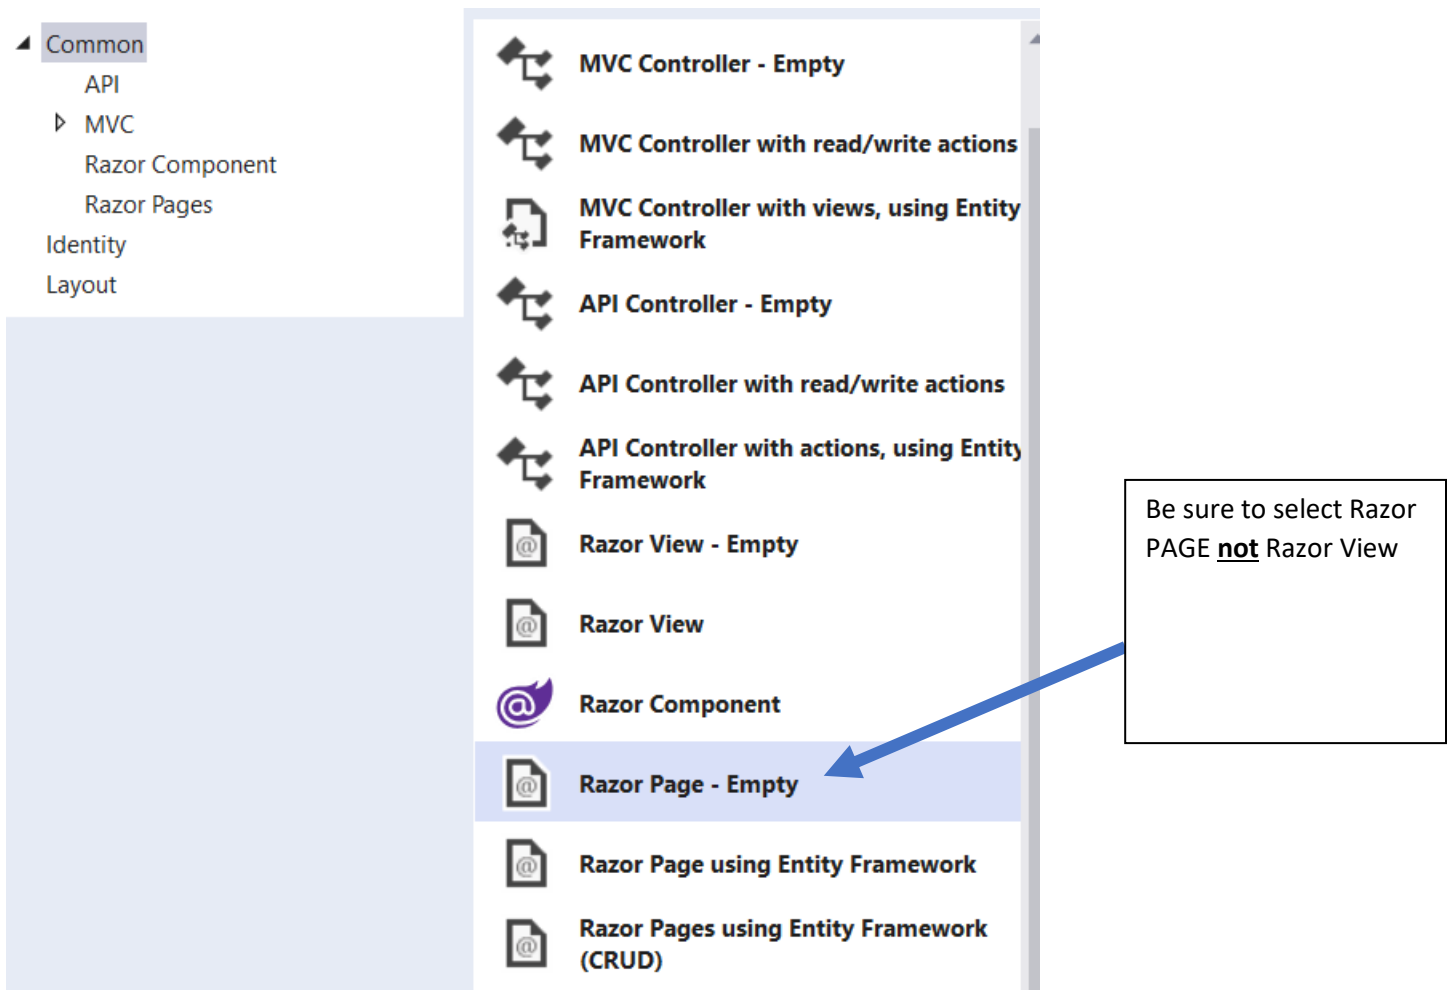

Another example of modification of a view.cs file to alter display name of a column, and also to change the way the data is displayed. Here I am controlling the date format display, as well as first name and last name displayed instead of fname and lname

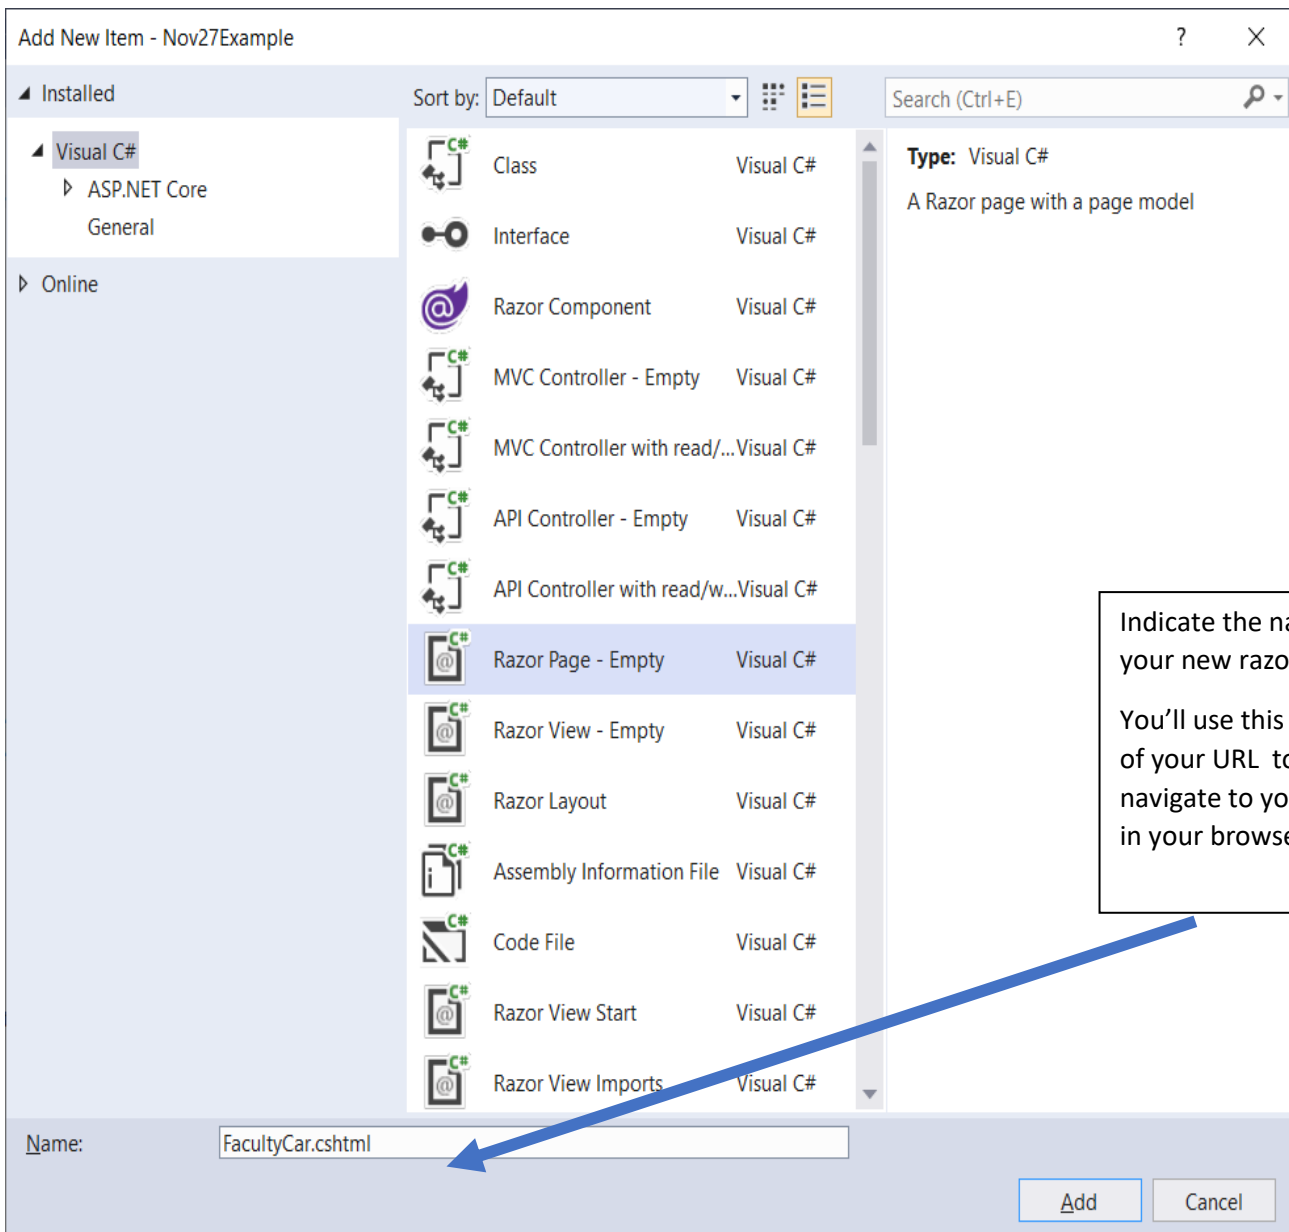

(C) Viewing data in a grid (tabular structure) from a View

Create an empty Razor page based on your dbContext.cs file

Click on the folder in which you want to create your .cshtml page for your view.

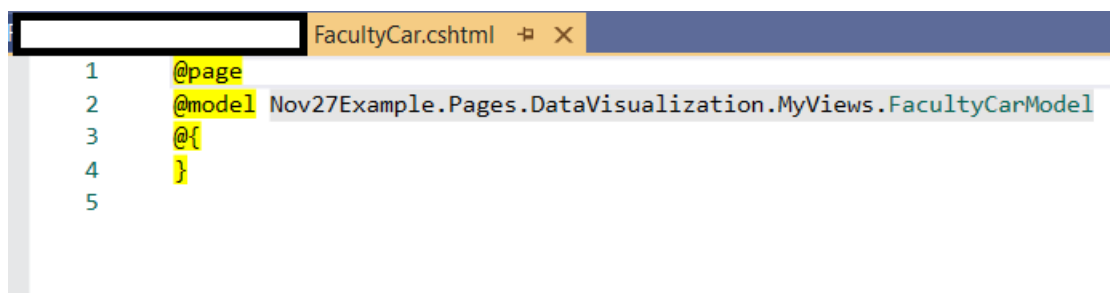

Add new item, and select

Upon creation of your Empty Razor Page will have a .cshtml part and a .cs part.

E.g in the example above my page was named FacultyCar.cshtml so I will see that in my solution explorer and when I click on it I will see FacultyCar.cs file.

This is what the .cs file behind your newly created razor page. We will amend it later to control our page display

```

FacultyCar.cshtml.cs
Nov27Example
1 using System;
2 using System.Collections.Generic;
3 using System.Linq;
4 using System.Threading.Tasks;
5 using Microsoft.AspNetCore.Mvc;
6 using Microsoft.AspNetCore.Mvc.RazorPages;
7
8 namespace Nov27Example.Pages.DataVisualization.MyViews
9 {
10     5 references
11     public class FacultyCarModel : PageModel
12     {
13         0 references
14         public void OnGet()
15         {
16         }
17     }

```

Add

using Microsoft.EntityFrameworkCore;

This is what the .cshtml file of your newly created razor page. We will amend it next to reflect the model of your view.cs file

Eliminate these sentences including Braces, and replace them with these shown below

private readonly Nov27Example.UzoParkingLotContext _context;

```

public FacultyCarGridModel(Nov27Example.UzoParkingLotContext context)
{
    _context = context;
}

```

public IList<VwFacultyCar> VwFacultyCar { get; set; }

```

public async Task OnGetAsync()
{
    VwFacultyCar = await _context.VwFacultyCars.ToListAsync();
}

```

Replace this with the name of your database and your dbContext.cs file

Name of the Razor page with the word Model after it

Name of your VWview.cs model file. Made from the

See the next page to see screen shot of what your razor page looks like after these changes.

```
FacultyCar.cshtml.cs* X
Nov27Example Nov27Example.Pages.DataVisualiza

1 using System;
2 using System.Collections.Generic;
3 using System.Linq;
4 using System.Threading.Tasks;
5 using Microsoft.AspNetCore.Mvc;
6 using Microsoft.AspNetCore.Mvc.RazorPages;
7 using Microsoft.EntityFrameworkCore;
8 namespace Nov27Example.Pages.DataVisualization.MyViews
9 {
10     6 references
11     public class FacultyCarModel : PageModel
12     {
13         private readonly Nov27Example.UzoParkingLotContext _context;
14
15         0 references
16         public FacultyCarModel(Nov27Example.UzoParkingLotContext context)
17         {
18             _context = context;
19
20         1 reference
21         public IList<VwFacultyCar> VwFacultyCar { get; set; }
22
23         0 references
24         public async Task OnGetAsync()
25         {
26             VwFacultyCar = await _context.VwFacultyCars.ToListAsync();
27         }
28 }
```

Now to amend your Razor page.cshtml file which depicts the data displayed on your page and any other styling and embellishments.

I am choosing to display my data in a table which I can style later on.

Note how column names are displayed, and note how an iteration occurs for every row in the table, modeling the data collection. See diagram on next page. The field names used are the exact spelling and case specified in the view.cs model file.

```

FacultyCar.cshtml*
1  @page
2  @model Nov27Example.Pages.DataVisualization.MyViews.FacultyCarModel
3  @{
4      ViewData["Title"] = "Faculty Cars";
5      Layout = "~/Pages/Shared/_Layout.cshtml";
6  }
7
8  <table id="myTable" class="table-striped table-bordered" style="width:100%;">
9
10     <thead>
11     <tr>
12     <th>
13         @Html.DisplayNameFor(model => model.VwFacultyCar[0].FacultyName)
14     </th>
15     <th>
16         @Html.DisplayNameFor(model => model.VwFacultyCar[0].Gender)
17     </th>
18     <th>
19         @Html.DisplayNameFor(model => model.VwFacultyCar[0].Car)
20     </th>
21     <th>
22         @Html.DisplayNameFor(model => model.VwFacultyCar[0].Color)
23     </th>
24     </tr>
25     </thead>
26     <tbody>
27     @foreach (var item in Model.VwFacultyCar)
28     {
29         <tr>
30         <td>
31             @Html.DisplayFor(modelItem => item.FacultyName)
32         </td>
33         <td>
34             @Html.DisplayFor(modelItem => item.Gender)
35         </td>
36         <td>
37             @Html.DisplayFor(modelItem => item.Car)
38         </td>
39         <td>
40             @Html.DisplayFor(modelItem => item.Color)
41         </td>
42         </tr>
43     }
44     </tbody>
45 </table>
46
47
48
49
50

```

The page when displayed looks like this:

Nov27Example [Home](#) [Privacy](#)

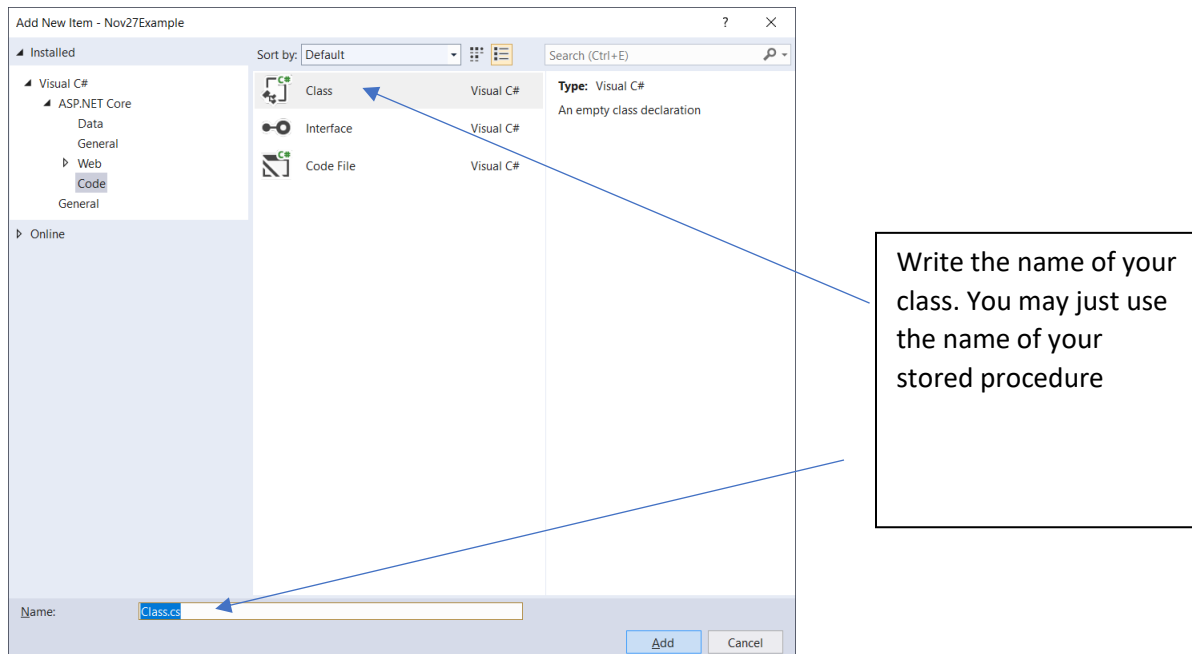

Faculty	Gender	Car	Color
Smith	M	Honda	Black
Iones	F	Honda	Red
Iones	M	Toyota	Blue
Williams	M	Toyota	White
Perez	F	BMW	Blue
Robinson	M	Mercedes	Red
Perez	M	BMW	Blue
Gardenia	M	Bugatti	Silver
Wellington	F	Bugatti	Red

(D)Viewing data from Stored Procedures (without parameters)

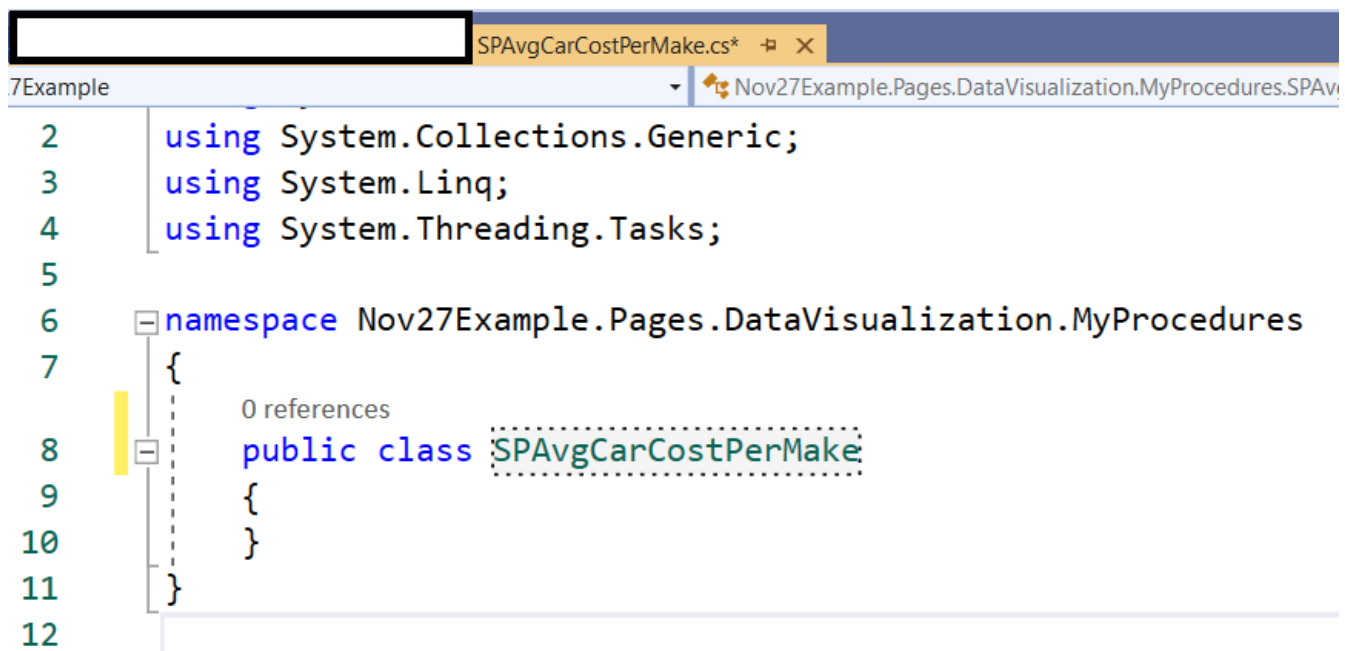

Unlike the Views which can be scaffolded into initial view.cs model files, we need to create our own model.cs files for each stored procedure, and include the models in our dbContext.cs file.

Then we can do what we did above in (C) and create an empty Razor page, modify the .cs file and display the .cshtml as we wish... in a table grid, or in a chart.

(1)Create a class declaration for a stored procedure. Select the folder where you want the razor page for this data, then Add new item, and select CLASS, when the window below pops open, put the name of your class

It will look like below

SPAvgCarCostPerMake.cs*

Nov27Example

Nov27Example.Pages.DataVisualization.MyProcedures.SPAvgC

```

1  using System;
2  using System.Collections.Generic;
3  using System.Linq;
4  using System.Threading.Tasks;
5  using System.ComponentModel.DataAnnotations;
6
7  namespace Nov27Example.Pages.DataVisualization.MyProcedures
8  {
9      0 references
10     public class SPAvgCarCostPerMake
11     {
12         0 references
13         public string Gender { get; set; }
14         [Display(Name = "Car Brand")]
15         0 references
16         public string make { get; set; }
17
18         [DisplayFormat(DataFormatString = "{0:C}")]
19         [Display(Name = "Average Cost")]
20         0 references
21         public string AverageCost { get; set; }
22     }
23 }

```

Remove.Pages.DataVisua
lization.MyPRocedurs

Which represent an
absolute path to your
class file

2) Add declarations to match the data generated by your store procedure in the order of occurrence. Keep the namespace area relative, by just using project name

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;
using System.ComponentModel.DataAnnotations;

namespace Nov27Example
{
    2 references
    public partial class spAvgCarCostPerMake
    {
        [Display(Name = "Car Brand")]
        1 reference
        public string make { get; set; }

        [DisplayFormat(DataFormatString = "{0:C}")]
        [Display(Name = "Average Cost")]
        1 reference
        public double AverageCost { get; set; }
    }
}

```

```
namespace NOV2/Example
```

In your DbContext.cs file, add one line for each stored procedure, using the same name as your stored procedure to avoid confusion

```
{  
    57 references  
    public partial class UzoParkingLotContext : DbContext  
    {  
        0 references  
        public UzoParkingLotContext(DbContextOptions<UzoParkingLotContext> options)  
            : base(options)  
        {  
        }  
        0 references  
        public virtual DbSet<spAvgCarCostPerMake> spAvgCarCostPerMake { get; set; }  
        0 references  
        public virtual DbSet<Mychart> Mycharts { get; set; }  
        14 references  
        public virtual DbSet<TblCar> TblCars { get; set; }  
        12 references  
    }  
}
```

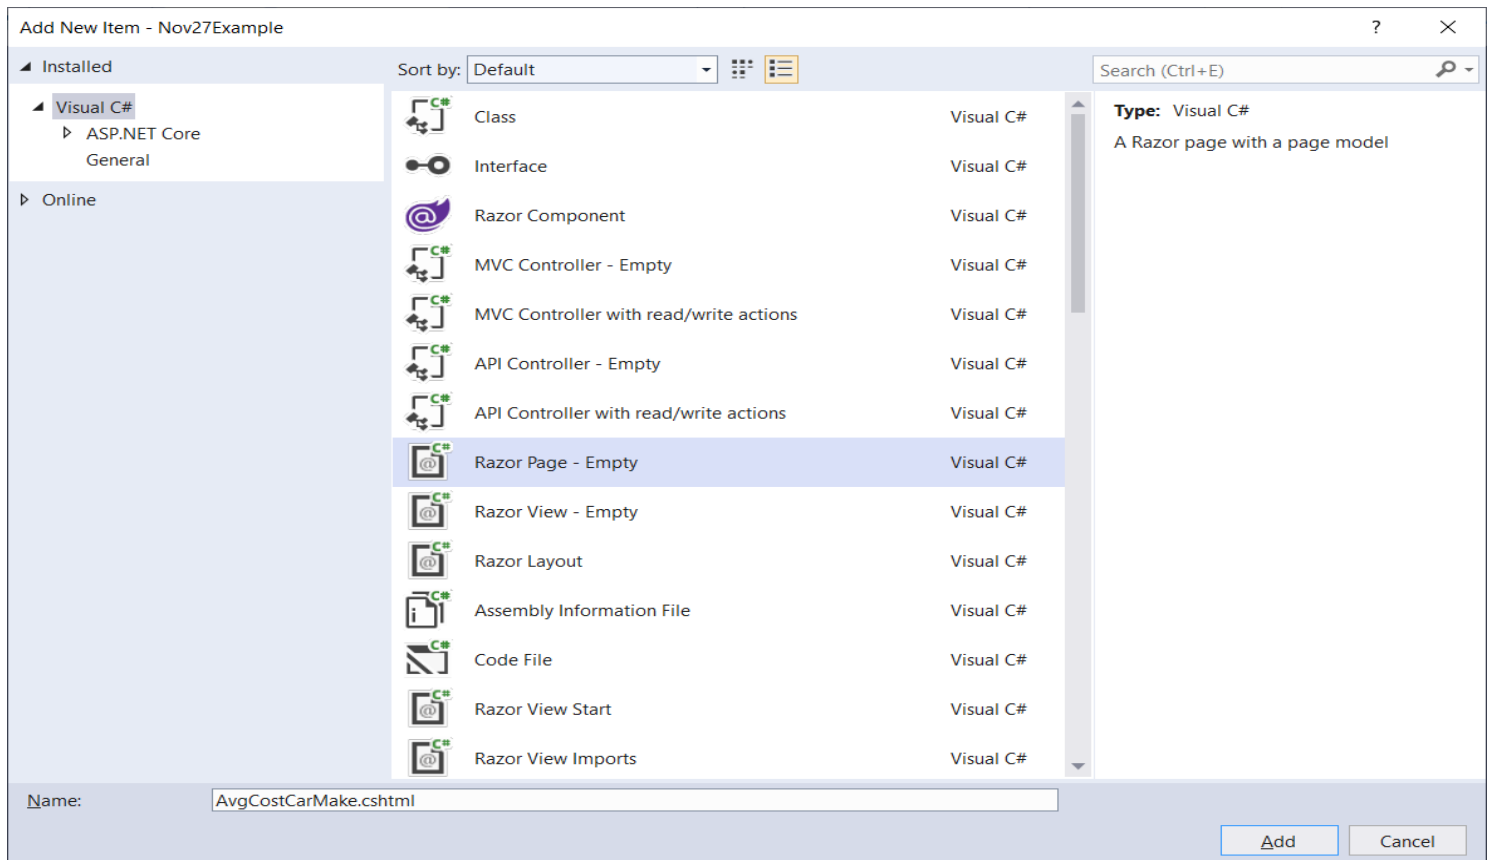

3) Adjust the DbContext.cs file to account for this new class of your stored procedure

Then scroll down in your DbContext.cs file to the part where the modelbuilders are defined. Insert a new modelbuilder for your stored procedure using the pattern below

Include an entity.Property for each column in your stored procedure.

```
0 references  
protected override void OnModelCreating(ModelBuilder modelBuilder)  
{  
    modelBuilder.Entity<spAvgCarCostPerMake>(entity =>  
    {  
        entity.HasNoKey();  
  
        entity.ToView("spAvgCarCostPerMake");  
  
        entity.Property(e => e.make);  
  
        entity.Property(e => e.AverageCost).HasColumnName("AverageCost");  
    });  
  
    modelBuilder.Entity<Mychart>(entity =>  
    {  
        entity.HasNoKey();  
    });  
}
```

- 3) Now to display data from the stored procedure on a razor.cshtml page, just like you did with the views. Click on the folder containing where the stored procedure.cs file is located, click Add new Item, and select empty Razor Page

Name the page. I usually name it with something declarative of what the stored procedure's function is. Do not use the same name as the stored procedure. (I removed the sp)

A .cshtml page will be created along with a .cs file behind it. Just like the views we will take care of the .cs file, then the display part on the .cshtml file.

- 4) Modifying the .cs file. It initially looks like the picture below

```
1  using System;
2  using System.Collections.Generic;
3  using System.Linq;
4  using System.Threading.Tasks;
5  using Microsoft.AspNetCore.Mvc;
6  using Microsoft.AspNetCore.Mvc.RazorPages;
7
8  namespace Nov27Example.Pages.DataVisualization.MyProcedures
9  {
10     5 references
11     public class AvgCostCarMakeModel : PageModel
12     {
13         0 references
14         public void OnGet()
15         {
16         }
17     }
```

5) Replace encircled portion above with the following: Also be sure to include at the top with other using statements

using Microsoft.EntityFrameworkCore;

```
        private readonly Nov27Example.UzoParkingLotContext _context;

        public AvgCarCostPerMakeModel(Nov27Example.UzoParkingLotContext context)
        {
            _context = context;
        }

        public IList<spAvgCarCostPerMake> spAvgCarCostPerMake { get; set; }

        public async Task OnGetAsync()
        {
            try
            {
                spAvgCarCostPerMake = await _context.spAvgCarCostPerMake.FromSqlRaw("Exec spAvgCarCostPerMake").ToListAsync();
            } catch (Exception)
            {
            }
        }

        public async Task OnPostAsync()
        {
            spAvgCarCostPerMake = await _context.spAvgCarCostPerMake.FromSqlRaw("Exec spAvgCarCostPerMake").ToListAsync();
        }
    }
```

Your .cs file will look like the figure on the next page

```

1 using System;
2 using System.Collections.Generic;
3 using System.Linq;
4 using System.Threading.Tasks;
5 using Microsoft.AspNetCore.Mvc;
6 using Microsoft.AspNetCore.Mvc.RazorPages;
7 using Microsoft.EntityFrameworkCore;
8
9 namespace Nov27Example.Pages.DataVisualization.MyProcedures
10 {
11     - references
12     public class AvgCarCostPerMakeModel : PageModel
13     {
14         private readonly Nov27Example.UzoParkingLotContext _context;
15
16         - references
17         public AvgCarCostPerMakeModel(Nov27Example.UzoParkingLotContext context)
18         {
19             _context = context;
20
21             - references
22             public IList<spAvgCarCostPerMake> spAvgCarCostPerMake { get; set; }
23
24             - references
25             public async Task OnGetAsync()
26             {
27                 try
28                 {
29                     spAvgCarCostPerMake = await _context.spAvgCarCostPerMake.FromSqlRaw("Exec spAvgCarCostPerMake").ToListAsync();
30                 }
31                 catch (Exception)
32                 {
33                 }
34             }
35
36             - references
37             public async Task OnPostAsync()
38             {
39                 spAvgCarCostPerMake = await _context.spAvgCarCostPerMake.FromSqlRaw("Exec spAvgCarCostPerMake").ToListAsync();
40             }
41         }
42     }
43 
```

Add using EntityFrameworkCore
Name of your cshtml file with Model
after it

Add this line declaring your
Database.Context file name with
project preceding it indicating
position in the directory structure

Instantiate context

Declare your storedprocedure model
file (.cs) as a collection

Declare onGet and onPost actions
With the ability to Exec raw sql statement.
Recall that in SQLserver we were able to
execute our stored procedures with exec
name of stored procedure

5) Now time to amend the .cshtml portion for the display. Initially it looks like this

```

AvgCostCarMake.cshtml
1 @page
2 @model Nov27Example.Pages.DataVisualization.MyProcedures.AvgCostCarMakeModel
3 @{
4 }
5 
```

Include the ViewData statement which will Title the page, and include the Layout statement indicating which page to use for your layout. The default is _Layout.cshtml

I chose to display my stored procedure results in a table. I used the first row of the Display Name for my column headings, and used a For loop to iterate through the rows to show collection content. (Just like with the Views earlier)

See next page

```

1  @page
2  @model Nov27Example.Pages.DataVisualization.MyProcedures.AvgCarCostPerMakeModel
3
4  @{
5      ViewData["Title"] = "Average Cost Per Make";
6      Layout = "~/Pages/Shared/_Layout.cshtml";
7  }
8
9  <table id="myTable" class="table-striped table-bordered" style="width:100%;">
10
11      <thead>
12      <tr>
13          <th>
14              @Html.DisplayNameFor(model => model.spAvgCarCostPerMake[0].make)
15          </th>
16          <th>
17              @Html.DisplayNameFor(model => model.spAvgCarCostPerMake[0].AverageCost)
18          </th>
19      </tr>
20      </thead>
21      <tbody>

(E) Viewing Data from Stored Procedures (with parameters)

In the case of Stored Procedures with parameters, everything is the same with (D) except in the .cs file of the top part of the .cshtml used to view it.

i.e. make your stored procedure model file as before, nameofstoredprocedure.cs from an empty Razor .cs page, include a new model builder in your DatabaseContextfile.cs for this new stored procedure.cs file, then create a Razor page in with which you will display the contents as above. At the beginning of this display.cshtml for your stored procedure with parameters, you must include a way to receive these parameter arguments. I use a form

```

<form class="form-horizontal" method="post" id="moi">
  <div class="form-group">
    <label for="myMake" class="col-sm-2 control-label">Brand desired:</label>
    <div class="col-sm-10">
      <input type="text" id="myMake" class="form-control" value="" name="myMake">
    </div>
  </div>
  <div class="form-group">
    <label for="myColor" class="col-sm-2 control-label">Cost:</label>
    <div class="col-sm-10">
      <input type="text" id="myColor" class="form-control" value="" name="myColor">
    </div>
  </div>
  <div class="form-group">
    <div class="col-sm-offset-2 col-sm-10">
      <button type="submit" class="btn btn-primary">Get Car Data</button>
    </div>
  </div>
</form>

```

Use the same id value for your parameters as you would use in the underlying .cs page

Mine are myMake and myColor

```

1  @page
2  @model Nov27Example.Pages.DataVisualization.MyProcedures.CarColorChoiceModel
3  @{
4      ViewData["Title"] = "Car Make and Color per Choice";
5      Layout = "~/Pages/Shared/_Layout.cshtml";
6  }
7
8
9  <form class="form-horizontal" method="post" id="moi">
10     <div class="form-group">
11         <label for="myMake" class="col-sm-2 control-label">Brand desired:</label>
12         <div class="col-sm-10">
13             <input type="text" id="myMake" class="form-control" value="" name="myMake">
14         </div>
15     </div>
16     <div class="form-group">
17         <label for="myColor" class="col-sm-2 control-label">Color:</label>
18         <div class="col-sm-10">
19             <input type="text" id="myColor" class="form-control" value="" name="myColor">
20         </div>
21     </div>
22     <div class="form-group">
23         <div class="col-sm-offset-2 col-sm-10">
24             <button type="submit" class="btn btn-primary">Get Car Data</button>
25         </div>
26     </div>
27 </form>
28
29 <table id="myTable" class="table-striped table-bordered" style="width:100%;">
30
31     <thead>
32         <tr>
33             <th>

```

My .CSHTML file looks like this

I included a form, with which to retrieve the parameters for the stored procedure, when the user clicks the button then the data is displayed.

On the next page I will display my .cs file which supports this .cshtml display

After checking that the data displays fine, I will later come back to my .cshtml file and add a div below the table, where I will serialize the data for my charts. I will hide this display when I am sure the data is good

Next Section we will discuss charts derived from the .cshtml pages.

My .cs file is on the next page

```
CarColorChoice.cshtml.cs X [REDACTED]

My next display shows what happens after I enter my arguments of ‘Honda’ and ‘Silver’

Car Make and Color per Choice X +

localhost:5001/DataVisualization/MyProcedures/CarColorChoice

Nov27Example Home Privacy

Brand desired:

Color:

Car Brand	Color	Car Year	First Name	Last Name
Honda	Silver	2009	Bob	Gomez
Honda	Silver	2004	Brian	Philips

(F) Making Charts from your .cshtml Razor pages

First of all I would only be charting data that has a definite category and one or more numeric data series.

So a good example of where I might do this would be on my stored procedure which features average cost per Car brand. That gives me a column for Brand and one for Avg Cost

As demonstrated from the google charts demonstrated on the first couple of pages of this document,

Your chart information must be in three parts

- invoke the google chart engine
- specify data
- specify options
- draw chart on page (within a div)

I reference the google chart engine.

I reference the javascript file with my script for manipulating my data array and setting chart options. You must also reference the function you want invoked to generate your file. You will see examples of these in pages 22-25.

The data is usually expected as an array of arrays, so I use the display name, and model items to build up this array.

I used the same data to create three different charts

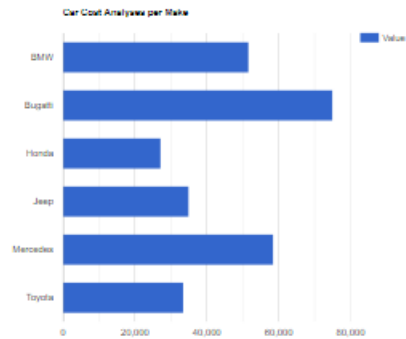

The created charts are on the next page.

```
AvgCarCostPerMake.cshtml
1 @page
2 @model Nov27Example.Pages.DataVisualization.MyProcedures.AvgCarCostPerMakeModel
3
4 @
5 ViewData["Title"] = "Average Cost Per Make";
6 Layout = "~/Pages/Shared/_Layout.cshtml";
7 <script src="https://www.gstatic.com/charts/loader.js"></script>
8 // for mychart.html</script>
9 <script src="~/js/mychart.js"></script>
10 <script>google.charts.setOnLoadCallback(myPieChartCostSumCount);</script>
11
12
13 <table id="myTable" class="table-striped table-bordered" style="width:100%;">
14
15
16 <thead>
17 <tr>
18 <th>
19 @Html.DisplayNameFor(model => model.spAvgCarCostPerMake[0].make)
20 </th>
21 <th>
22 @Html.DisplayNameFor(model => model.spAvgCarCostPerMake[0].AverageCost)
23 </th>
24 </tr>
25 </thead>
26
27 <tbody>
28
29 @foreach (var item in Model.spAvgCarCostPerMake)
30 {
31 <tr>
32 <td>
33 @Html.DisplayFor(modelItem => item.make)
34 </td>
35 <td>
36 @Html.DisplayFor(modelItem => item.AverageCost)
37 </td>
38 </tr>
39
40 }
41 </tbody>
42 </table>
43

52
53 }
54
55 </div>
56
57
58 <div id="myBarChart"></div>
59 <br />
60 <div id="myPieChart"></div>
61 <br />
62 <div id="myLineChart"></div>
63
```

Nov27Example Home Privacy

Car Brand	Average Cost
BMW	\$51,666.67
Bugatti	\$75,000.00
Honda	\$27,176.60
Jeep	\$35,000.00
Mercedes	\$58,601.60
Toyota	\$33,438.75

[["BMW", 51666.67], ["Bugatti", 75000], ["Honda", 27176.6], ["Jeep", 35000], ["Mercedes", 58601.6], ["Toyota", 33438.75]]

I purposely let the raw data so you could see how the generated data looks. I normally would set the `<div>` style attribute to `display:none`, so that it remains invisible.

My `<div>` id is `mydata`, and you will see how this is referenced in my javascript file `mychart.js`

(PAGES 22 AND 23)

Which contains all my functions for each chart.

The function being used here for all three charts is `myPieChartCostSumCount()`

Which grabs the data from the `<div>` `mydata`, does some apostrophe replacements, concatenates the data into the form expected (array of arrays) then draws the same data three times specifying different options for each one.

Page 22 Shows my javascript file for generic charts

Page 23 shows my javascript function that generates chart from data from my razor .cshtml page obtained from the stored procedure

Be sure to include you .js files in your layout or at the top of relevant page. See page 20

This is mycharts.js

// Load packages ONCE as seen below

```
google.charts.load('current', {packages: ['corechart'] });
```

I'll point out what you need

Load google core chart packages

ALWAYS FIRST LINE

```
function myDrawPieChart() {  
  // Define the chart to be drawn.  
  var data = new google.visualization.DataTable();  
  data.addColumn('string', 'Element');  
  data.addColumn('number', 'Percentage');  
  data.addRows([  
    ['Nitrogen', 0.78],  
    ['Oxygen', 0.21],  
    ['Other', 0.01]  
  ]);
```

Example of a typical Chart

The function first defines data

Then provides options

Then draws chart based on type specified and in the <div> Identified by the document.getElementById(" ")

// options to use map

```
var options_pie = {title:'Pie Chart: Air Constitution',  
  width:500, height:500};
```

// Instantiate and draw the chart.

```
var chart = new google.visualization.PieChart(document.getElementById('myPieChart'));  
chart.draw(data, options_pie);  
}
```

// for multiplecharts2.html different chart styles, same data

```
function drawMultipleCharts() {
```

```
  var data = new google.visualization.DataTable();  
  data.addColumn('string', 'Topping');  
  data.addColumn('number', 'Slices');  
  data.addRows([  
    ['Mushrooms', 3],  
    ['Onions', 1],  
    ['Olives', 1],  
    ['Zucchini', 1],  
    ['Pepperoni', 2]  
  ]);
```

Example of multiple chart types drawn with the same data

The function first defines data

Then provides options

Then draws chart based on type specified and in the <div> Identified by the document.getElementById(" ")

```
  var piechart_options = {  
    title: 'Pie Chart: How Much Pizza I Ate Last Night',  
    width: 400,  
    height: 300  
  };
```

```
  var piechart = new google.visualization.PieChart(document.getElementById('piechart_div'));  
  piechart.draw(data, piechart_options); // draw pie chart
```

```
  var barchart_options = {  
    title: 'Barchart: How Much Pizza I Ate Last Night',  
    width: 400,  
    height: 300,  
    legend: 'none'  
  };
```

```
  var barchart = new google.visualization.BarChart(document.getElementById('barchart_div'));  
  barchart.draw(data, barchart_options); // draw bar chart  
}
```

//TO CREATE DATA FROM STORED PROCEDURE

```
//Draw chart from stored procedure
function myPieChartCostSumCount() {
  // Define the chart to be drawn.
  var data = new google.visualization.DataTable();
  data.addColumn('string', 'Category');
  data.addColumn('number', 'Value');
  var x = document.getElementById("mydata").innerHTML;
  x = x.trim();
  if (x.charAt(0) == ",")
  {
    x = x.substring(1);
  }
  //*****
  // alert(x);
  var z = x.replace(/"/g, "!"); // switch " to ' by first replacing " with !
  x = z.replace(/'/g, "~"); // switch ' to " by first replacing with ~

  z = x.replace(/~/g, ""); // then switch ~ to " and ! to '
  x = z.replace(/!/g, "");

  // alert(x);
  var myChartData = JSON.parse("[ " + x + " ]");

  data.addRows(myChartData); // add parsed data (myChartData) to array called data

  // options for Pie chart
  var options_pie = {
    title: 'Car Cost Analyses per Make',
    width: 700, height: 700
  };

  // options for Bar chart
  var options_bar = {
    title: 'Car Cost Analyses per Make',
    width: 700, height: 700
  };

  // options for Line chart
  var options_line = {
    curveType: 'function',
    legend: { position: 'bottom' }
  };
  // Instantiate and draw the Line chart.
  var chart = new google.visualization.LineChart(document.getElementById('myLineChart'));
  chart.draw(data, options_line);

  // Instantiate and draw the Bar chart.
  var chartBar = new google.visualization.BarChart(document.getElementById('myBarChart'));
  chartBar.draw(data, options_bar);

  // Instantiate and draw Pie chart.
  var chartPie = new google.visualization.PieChart(document.getElementById('myPieChart'));
  chartPie.draw(data, options_pie);
}
```

Example of chart drawn from data retrieved from my .cshtml Razor Page.

I named a <div> mydata, before starting.

The function first defines data, then retrieves its contents from my <div id="mydata">

I replace the apostrophes to "" and arrange the data as an array of arrays.

Then provides options

I use the same data for multiple chart types so I give each one its own set of options.

Then draws chart based on type specified and in the <div> Identified by the document.getElementById(" ")
